▼ **Abstract**
Article abstract-Multiple factors appear to contribute to the expression of Alzheimer's disease (AD). About 30% of cases of dementia of the Alzheimer's type can be attributed to genetic factors. These observations raise the possibility of identifying multiple interventions that may modify the disease process and, therefore, the clinical expression of the dementia. Prominent among factors that may contribute to dementia and, specifically, to dementia of the Alzheimer's type

View Abstract

An inverse association between **estrogen therapy** (ET) and **Alzheimer disease** (AD) has been reported in some, but not in all studies. We investigated the association between ET and AD in postmenopausal women using a population-based case-control design. Women who developed AD from 1985 through 1989 in Rochester, MN (cases, n=264) were individually matched by age (+/-1 y) to control women free of dementia from the same population (controls, n=264). ET exposure (>=6 mo after menopause) was ascertained by abstracting the complete medical records archived in the records-linkage system of the Rochester Epidemiology Project. The frequency of ET use was similar in cases (11.4%) and controls (10.6%; odds ratio=1.10; 95% confidence interval (CI)=0.63-1.93). However, cases who used ET had a suggestive trend for an earlier age at stroke (mean age at stroke=69.0 years in cases vs 69.4 years in controls; P=0.04). In addition, cases who used ET had a higher frequency of smoking (49.0% vs 44.0%; P=0.001). In multivariate analyses, ET use was not associated with AD overall, we observed an interaction between smoking and ET. The odds ratio of AD in ET users was 4.55 (95% CI=1.33-15.53) among smokers, whereas it was 0.63 (95% CI=0.28-1.44) among nonsmokers. These findings suggest that smoking may confirm a significant association between ET and AD overall; however, the possible interaction with smoking deserves further study.
